

Troubleshooting & Common Errors Reference

Technical Support Protocol

March 5, 2026

Git Troubleshooting

Git Pathspec Error

Explanation: Git cannot find the specified file or directory path in the current branch.

Solution: Check the file path and ensure it exists. Verify spelling and case-sensitivity (macOS is often case-insensitive, but Git can be sensitive).

Git Push Rejected

Explanation: Your local repository is behind the remote repository (someone else has pushed changes).

Solution: Run `git pull` first to fetch and merge remote changes, resolve any conflicts, then attempt the push again.

Git Merge Conflict

Explanation: Occurs when changes in different branches conflict on the same lines of the same file while merging.

Solution: Open the affected files, resolve the conflicts manually (look for <<<<<< and >>>>>> markers), then stage and commit the resolution.

Python Troubleshooting

Python FileNotFoundError

Explanation: The Python interpreter cannot find the file specified at the provided path.

Solution: Ensure the file is inside the allowed directory and the path provided to the script is correct relative to the current working directory.

Python Syntax Error

Explanation: The Python code has incorrect syntax that prevents it from running.

Solution: Review the code for missing colons, mismatched parentheses, or incorrect indentation (Python relies on 4-space indentation).

System & Terminal Troubleshooting

System Command Not Found

Explanation: The macOS terminal (shell) cannot locate the executable command you entered.

Solution: Verify spelling and the application path. Check your shell configuration (e.g., `.zshrc`) to ensure the command's directory is in your `PATH`.

Permission Denied

Explanation: The Terminal or Python script cannot access a file or folder due to restricted system permissions.

Solution: Check file permissions using `ls -l` and use `chmod` to modify them if necessary. Ensure you have the rights to the parent directory.

File Already Exists

Explanation: You are attempting to create or rename a file/folder to a name that is already taken in that directory.

Solution: Rename or remove the existing file before creating a new one, or use a conditional check in Python to handle pre-existing files.

Command Not Allowed

Explanation: The security settings of the assistant environment prevent this specific command from executing.

Solution: Only safe, predefined commands are permitted. Consult the `ALLOWED_COMMANDS` list in your environment settings.
